

App Flow

MaaSaathi — based on the SipnaHackX repository

MaaSaathi is a single-page app (index.html) backed by an Express server. Data is kept in the browser's localStorage for instant use, and optionally synced to a server-side JSON database for persistence across devices.

- Step 1 — Profile setup:** The user enters name, preferred language, pregnancy status, estimated due date (EDD), city, doctor/hospital details, and an emergency contact.
- Step 2 — Local + server save:** The profile is saved to browser localStorage immediately, and can be synced to the server via POST /api/user/profile and POST /api/records/sync.
- Step 3 — Dashboard loads:** The app calculates the current pregnancy week from the EDD and fetches appointments, checklists, and records via GET /api/records/all.
- Step 4 — User explores Learn content:** Multilingual (English/Hindi) awareness cards cover pregnancy health, vaccination, nutrition, and newborn care.
- Step 5 — User logs data:** Symptoms, kick-counting sessions, appointments, and clinical records are added through dedicated endpoints (/api/symptoms, /api/kicks, /api/appointments, /api/clinical-records).
- Step 6 — User asks the AI assistant:** A question is sent to POST /api/chat along with relevant saved context (name, pregnancy week, next appointment, recent symptoms). The server calls Gemini or Groq under a safety system prompt, or returns a demo reply if no API key is configured.
- Step 7 — Warning-sign safety check:** If the message contains a possible warning sign, the assistant does not diagnose — it recommends urgent professional care and directs the user to the Get Help Now / emergency page.
- Step 8 — Data persists:** Every change is written back to server/data/maasaathi_db.json through an atomic write, and the user can export or import a full JSON backup at any time.
