

Implementation Plan

MaaSaathi — as reflected in the SipnaHackX repository

#	Phase	What it covers
1	Frontend prototype	Build the single-page app (index.html) with HTML/CSS/JS, covering profile setup, dashboard, Learn section, and trackers, using localStorage for instant persistence.
2	Embedded JSON database	Add server/database.js: an atomic-write JSON document store (server/data/maasaathi_db.json) with per-user documents for profile, appointments, records, symptoms, and more.
3	REST API layer	Build server/index.js with Express: CRUD endpoints for appointments and clinical records, plus sync, profile, symptom, and kick-session routes.
4	AI chat integration	Add POST /api/chat, wiring Gemini and Groq under a safety system prompt that blocks diagnosis and redirects warning signs to urgent-care guidance; demo replies cover the no-API-key case.
5	Multilingual support	Wire English/Hindi throughout the UI and AI responses, driven by the user's saved language setting.
6	Backup & deployment	Add export/import endpoints for full JSON backups, then deploy the app (served via Express static + catch-all route) to Vercel at sipna-hack-x.vercel.app.

Tech Stack

Frontend: HTML, CSS, JavaScript (single index.html). Backend: Node.js + Express, CORS, dotenv. AI: Gemini or Groq (OpenAI-compatible) via node-fetch. Storage: browser localStorage plus an embedded JSON file database. Hosting: Vercel.
